A B S T R A C T

The single crystals of bis[1-(diaminomethylene)thiouron-1-ium] fumarate were grown using a solution growth technique. The compound crystallises in the centrosymmetric P21/c space group of the monoclinic system. The conformation of the fumarate anion is not strictly planar, but twisted. Both arms of the cation are oppositely rotated by 13.8(1)° around the C–N bonds involving the central N atom. The fumarate(–) anion is also non-planar, both deprotonated carboxylate groups are oppositely turned in relation to the planar carbon chain. The arrangement of oppositely charged components, i.e. 1-(diaminomethylene)thiourea-1-ium cation and fumarate(2–) anions in the crystal is mainly determined by ionic and hydrogen-bonding interactions forming three-dimensional network. The compound was also characterised by the FT-IR and Raman spectroscopy. The characteristic bands of the NH2, C=O and COO– groups as well as of C=N–C, N=C–N, C=COO and C=C–C skeletal groups are discussed. The vibrational assignments have been supported by the isotropic frequency shift.

1. Introduction

Studies on the self-assembly of organic and inorganic molecules in the solid state have become intense research activity due to their physical and chemical properties as well as due to their applications in the field of material sciences, molecular biology, pharmaceutical sciences, supramolecular chemistry and the crystal engineering [1–5]. The directional interactions resulting from the multiple hydrogen bonds with the neighbours, mainly the O–H···O, O–H···N and N–H···O or N–H···N, play an important role in molecular recognition and self-assembly of organic or organic–inorganic molecules in solids [6–8]. Many different self-complementary hydrogen bonding groups can be used to control association in supramolecular chemistry to produce the programmed arrangement, such as chains, sheets, ribbons, tapes and rosettes [9–14].

One of the methods used for obtaining new materials is based on the acid-base ionic and directional hydrogen-bonding interactions and molecular recognition [15–17]. Some of the acid-base materials with ionic and hydrogen-bonding interactions exhibit non-linear optical properties [18–20]. In these materials the acid part of the molecular crystals is responsible for favourable chemical and physical properties due to the directional and strong hydrogen bonds, while the base organic part with the relatively strong hyperpolarisability is mainly responsible for non-linear optical properties [21,22].

The crystalline 2-imino-4-thiobiuret (Aldrich, CAS No. 2114-02-05) is in fact the tautomeric form of 1-(diaminomethylene)thiourea (Scheme 1) as has been identified by the X-ray single crystal analysis [23].

Both tautomers, i.e., 2-imino-4-thiobiuret and 1-(diaminomethylene)thiourea, are potentially interesting compounds as an organic base and can be used in the crystal engineering for obtaining base-acid materials with extended hydrogen bonds framework, since they contain several active hydrogen bonding sites (Scheme 1). Additionally, both tautomers can act as N,N- or N,S-coordinating ligands forming several types of complexes with metal ions [24–26]. Besides, the known Pt and Pd complexes with these tautomers, the 1-(diaminomethylene)thiourea or its 2-imino-4-thiobiuret tautomer can form salts, since they contain the basic N atom with the lone-pair of electrons that can accept the H+ forming positively charged cations that together with the oppositely charged partners can form extended hydrogen bonded networks in solids [27–31]. In the present work, we investigate the crystal structure of 1-(diaminomethylene)thiourea-1-ium fumarate by the X-ray single crystal diffraction method. The compound was also characterised by vibrational spectroscopy, and the results are discussed and compared with the data obtained for a neutral 1-(diaminomethylene)thiourea molecule.
2. Experimental

All materials were commercially available and used as received. Elemental analysis was carried out with a Perkin-Elmer 240 elemental analyzer.

2.1. Preparation of bis[1-(diaminomethylene)thiourea-1-ium] fumarate

Commercially available 2-imino-4-thiobiuret (amidinothiourea, Aldrich, CAS No. 2114-02-05), which is in fact the tautomeric form 1-(diaminomethylene)thiourea and fumaric acid (Aldrich, purity of 99%) were added to hot water in a molar proportion of 1:1. When the solution became homogenous it was cooled slowly and kept at room temperature. After several days, transparent colourless crystals were formed. Anal. Calculated for C_{12}H_{18}N_{5}S_{2}: C, 27.28%; H, 4.54%; N, 31.80%; O, 18.19% and S, 18.19%. Found: C, 27.33%; H, 4.51%; N, 31.82%; O, 18.22% and S, 18.12%.

2.2. X-ray data collection

X-ray intensity data for the crystal were collected using graphite monochromatic Mo Kα radiation on a four-circle κ geometry KUMA KM-4 diffractometer with a two-dimensional area CCD detector. The ω-scan technique with Δω = 1.0° for each image was used for data collection. The 760 images for six different runs covering over 99% of the Ewald sphere were performed. The unit cell parameters were refined by the least-squares methods on the basis of 1522 reflections. One image was used as a standard after every 40 images for monitoring of the crystal stability and data collection, and no correction on the relative intensity variations was necessary. 10190 reflections (2045 independent, Rint = 0.0210) were measured up to 59.0° in 2θ. Data collections were made using the CrysAlis CCD program [32]. Integration, scaling of the reflections, correction for Lorentz and polarisation effects and absorption corrections were performed using the CrysAlis Red program [32]. The structure was solved by the direct methods using SHELXS-97 and refined using SHELXL-97 programs [33]. The hydrogen atoms were located in difference Fourier maps and refined. The final difference Fourier maps showed no peaks of chemical significance. The largest peaks on the final Δρ map were +0.222 and −0.230 e Å⁻³. Details of the data collection parameters, crystallographic data and final agreement parameters are collected in Table 1. Visualisation of the structure was made with the Diamond 3.0 program [34]. Selected geometrical parameters are listed in Table 2 and the geometry of hydrogen-bonding interactions are collected in Table 3.

2.3. Vibrational spectra measurements

The vibrational measurements were carried out at room temperature. The Fourier transform infrared spectrum was recorded from nujol mulls between 4000 and 400 cm⁻¹ on a Bruker IFS 113 V FT-IR. The Fourier Transform Raman spectrum was recorded on a FRA-106 attached to the Bruker 113 V FT-IR spectrometer equipped with Ge detector cooled to liquid nitrogen temperature.

**Resolution**: Resolution was set up to 2 cm⁻¹, signal/noise ratio was established by 32 scans. Nd⁺⁺:YAG air-cooled diode pumped laser of power ca. 200 mW was used as an exciting source. The incident laser excitation was 1064 nm. The scattered light was collected at the angle of 180° in the region of 3600–80 cm⁻¹, resolution 2 cm⁻¹, 256 scans. Deuterated D⁺⁺ bis[1-(diaminomethylene)thiourea-1-ium] fumarate was prepared by the usual reaction with heavy water. The crystals of bis[1-(diaminomethylene)thiourea-1-ium] fumarate were dissolved in heavy water, and was left in the atmosphere saturated with heavy water for 2 weeks in order to avoid the contamination of the crystals. The procedure was repeated twice. The
obtained deuterated analogue crystallizes similar as H-compound in monoclinic system (P2₁/c) with quite similar lattice parameters.

### 3. Results and discussion

Good quality single crystals of bis[1-(diaminomethylene)thiouron-1-ium] fumarate suitable for the X-ray analysis were obtained from water solution at room temperature. The X-ray single crystal analysis shows that both carboxyl groups of fumaric acid are deprotonated (Fig. 1). In addition, the X-ray analysis revealed that only a half of the deprotonated fumarate(2⁻) anion is independent, since it lies at the inversion center. The oppositely charged units, i.e. 1-(diaminomethylene)thiouron-1-ium cation and fumarate anion interact via two pairs of almost linear N–H···O hydrogen bonds with a graph of $R_2^2(8)$ forming bis[1-(diaminomethylene)thiouron-1-ium] fumarate molecular complex (Fig. 2).

The 1-(diaminomethylene)thiouron-1-ium cation in the crystal is not strictly planar, but twisted. Both arms of the cation are oppositely rotated around the C–N bonds involving the central N1 atom (Fig. 1). The dihedral angle between the N1/C1/S1/N2 and N1/C2/N3/N4 planes is 13.8(1)°.

Forming the π bond of the C1–S1 and C2–N1 double bonds as observed in neutral molecule (see Scheme 1) are also perpendicular to the plane. Therefore due to symmetry of the p orbitals the planarization of the amine nitrogen atoms. This indicates that the lone-pair of electrons occupies the p orbital that is perpendicular to the plane of NH₂ group. Additionally, the p orbitals of the C, S and N atoms

*Fig. 2.* A view of hydrogen bonded bis[1-(diaminomethylene)thiouron-1-ium] fumarate molecular complex. Symmetry code: $i = -x, -y, 1 - z$.

*Fig. 3.* Molecular packing of bis[1-(diaminomethylene)thiouron-1-ium] fumarate in the unit cell.

*Fig. 4.* A view of hydrogen-bonding interaction of bis[1-(diaminomethylene)thiouron-1-ium] fumarate molecular complex with the neighbours. Symmetry code: $i = -x, -y, 1 - z$; $ii = 1 - x, -0.5 + y, 1.5 - z$; $iii = -x, -0.5 + y, -0.5 + z$; $iv = 1 + x, 0.5 + y, -0.5 + z$; $v = x, 0.5 - y, 0.5 + z$.
The delocalisation of π bonds is possible and leads to the elongation of the double C1=Si and C2=N1 bonds and to shortening of other C–N bonds linking the amine groups (Table 2). Thus the bond order of the C−NH2 bonds is greater than of the both C−N bonds involving the central N1 atom.

The centrosymmetric fumarate(2−) anion also exhibits twisted conformation as both COO− groups are turned oppositely as in the present structure, in several structures of double C=O groups linking the amine groups (Table 2). Thus the bond order of the C−NH2 bonds is greater than of the both C−N bonds involving the central N1 atom.

The almost equal C−O distances of the COO− point to the delocalisation of the charge over both C−O bonds. The single C3−C4 bond is slightly shorter than a typical double C=C single bond and the double C4−C0 is slightly longer than the typical double C=C bond [37]. The values of the C−C bond distances in the carbon chain together with the sp2 hybridisation of the orbitals on the all carbon atoms indicate a partial delocalisation of the π bond over the whole carbon skeleton.

The oppositely charged units, i.e., 1-(diaminomethylene)thiouron-1-ium cation and fumarate anion interact via two pairs of almost linear N−H⋯O hydrogen bonds with a graph of R21(8) forming in the crystal the bis[1-(diaminomethylene)thiouron-1-ium] fumarate molecular complex (Fig. 3). The center of the C4−C0 bond of the molecular complex lies at the inversion center. The bis[1-(diaminomethylene)thiouron-1-ium] fumarate molecular complex interacts with the neighbours via N−H⋯O hydrogen bonds (see Fig. 4) forming a three-dimensional hydrogen bonded network (Fig. 3).

The FT-IR spectra of bis[1-(diaminomethylene)thiouron-1-ium] fumarate and its deuterated analogue are shown in Fig. 5a and b, respectively, while the Raman spectrum for protiated complex is given in Fig. 6. The bands corresponding to the vibration of the functional groups were identified with the aid of infrared correlation charts [44,45]. In addition, the spectra of bis[1-(diaminomethylene)thiouron-1-ium] fumarate are compared with the spectra of 1-(diaminomethylene)thiourea [46] and of fumaric acid [47,48]. The title compound has several functional and skeletal groups such as

![Fig. 5. Room temperature FT-IR spectrum of bis[1-(diaminomethylene)thiouron-1-ium] fumarate (a) and its deuterated analogue (b).](image)

![Fig. 6. Raman spectrum of bis[1-(diaminomethylene)thiouron-1-ium] fumarate.](image)
as three NH₂, C=S, C=N–C, N–C=N and N–C=S groups in the cation and COO⁻, C=–C, C=COO⁻, C=C–C and C=H in the anion. A careful inspection of the IR spectrum ([Fig. 5a]) shows medium-strength intensity bands at 3378 and 3353 cm⁻¹ and the weaker bands at 3265 and 3116 cm⁻¹ that can be attributed to the asymmetric and symmetric stretching of NH₂ groups of the 1-(diaminomethylene)thiouron-1-ium cation. These bands, as expected, are shifted in the IR spectrum of deuterated analogue ([Fig. 5b]) to N-D-O hydrogen bonds with N–D distances ranging from 2.708 to 2.943 Å. This reveals as a broad band in the range of 3300–2500 cm⁻¹, which is shifted to ~1950 cm⁻¹ in the spectrum of deuterated analogue. Additionally, the broad band in the region of 1400–1100 cm⁻¹ of the 1-(diaminomethylene)thiouron-1-ium cation and fumarate dianion are not planar, they exhibit twisted conformation. The arrangement of these oppositely charged units in the crystal is mainly determined by the ionic and the N–H–O hydrogen bonds forming three-dimensional network. Comparison of the IR spectra of bis[1-(diaminomethylene)thiouron-1-ium] fumarate and its deuterated analogue clearly shows marked differences in the regions of vibrations of the amine and imine groups as well as in the region of the N–H–O hydrogen bonds.

**Appendix A. Supplementary material**

Additional material comprising full details of the X-ray data collection and final refinement parameters including anisotropic thermal parameters and full list of the bond lengths and angles have been deposited with the Cambridge Crystallographic Data Center in the CIF format as supplementary Publications No. CCDC 798711. Copies of the data can be obtained free of charge on the application to CCDC, 12 Union Road, Cambridge, CB21EZ, UK (fax: (+44) 1223 336 033; email: deposit@ccdc.cam.ac.uk). Supplementary data associated with this article can be found, in the online version, at doi:10.1016/j.molstruc.2010.11.075.
